## 9. Numerical linear algebra background

- matrix structure and algorithm complexity
- solving linear equations with factored matrices
- LU, Cholesky, $\operatorname{LDL}^{\top}$ factorization
- block elimination and the matrix inversion lemma
- solving underdetermined equations

## Matrix structure and algorithm complexity

cost (execution time) of solving $A x=b$ with $A \in \mathbf{R}^{n \times n}$

- for general methods, grows as $n^{3}$
- less if $A$ is structured (banded, sparse, Toeplitz, ...)

## Flop counts

- flop (floating-point operation): one addition, subtraction, multiplication, or division of two floating-point numbers
- to estimate complexity of an algorithm: express number of flops as a (polynomial) function of the problem dimensions, and simplify by keeping only the leading terms
- not an accurate predictor of computation time on modern computers
- useful as a rough estimate of complexity

## Basic operations

Vector-vector operations $\left(x, y \in \mathbf{R}^{n}\right)$

- inner product $x^{T} y: 2 n-1$ flops (or $2 n$ if $n$ is large)
- sum $x+y$, scalar multiplication $\alpha x$ : $n$ flops

Matrix-vector product $y=A x$ with $A \in \mathbf{R}^{m \times n}$

- $m(2 n-1)$ flops (or $2 m n$ if $n$ large)
- $2 N$ if $A$ is sparse with $N$ nonzero elements
- $2 p(n+m)$ if $A$ is given as $A=U V^{T}, U \in \mathbf{R}^{m \times p}, V \in \mathbf{R}^{n \times p}$

Matrix-matrix product $C=A B$ with $A \in \mathbf{R}^{m \times n}, B \in \mathbf{R}^{n \times p}$

- $m p(2 n-1)$ flops (or $2 m n p$ if $n$ large)
- less if $A$ and/or $B$ are sparse
- $(1 / 2) m(m+1)(2 n-1) \approx m^{2} n$ if $m=p$ and $C$ symmetric

## Linear equations that are easy to solve

Diagonal matrices $\left(a_{i j}=0\right.$ if $\left.i \neq j\right)$ : $n$ flops

$$
x=A^{-1} b=\left(b_{1} / a_{11}, \ldots, b_{n} / a_{n n}\right)
$$

Lower triangular ( $a_{i j}=0$ if $j>i$ ): $n^{2}$ flops

$$
\begin{aligned}
x_{1} & :=b_{1} / a_{11} \\
x_{2} & :=\left(b_{2}-a_{21} x_{1}\right) / a_{22} \\
x_{3} & :=\left(b_{3}-a_{31} x_{1}-a_{32} x_{2}\right) / a_{33} \\
& : \\
x_{n} & :=\left(b_{n}-a_{n 1} x_{1}-a_{n 2} x_{2}-\cdots-a_{n, n-1} x_{n-1}\right) / a_{n n}
\end{aligned}
$$

called forward substitution
Upper triangular ( $a_{i j}=0$ if $j<i$ ): $n^{2}$ flops via backward substitution

## Linear equations that are easy to solve

Orthogonal matrices: $A^{-1}=A^{T}$

- $2 n^{2}$ flops to compute $x=A^{T} b$ for general $A$
- less with structure, e.g., if $A=I-2 u u^{T}$ with $\|u\|_{2}=1$, we can compute $x=A^{T} b=b-2\left(u^{T} b\right) u$ in $4 n$ flops

Permutation matrices:

$$
a_{i j}= \begin{cases}1 & j=\pi_{i} \\ 0 & \text { otherwise }\end{cases}
$$

where $\pi=\left(\pi_{1}, \pi_{2}, \ldots, \pi_{n}\right)$ is a permutation of $(1,2, \ldots, n)$

- interpretation: $A x=\left(x_{\pi_{1}}, \ldots, x_{\pi_{n}}\right)$
- satisfies $A^{-1}=A^{T}$, hence cost of solving $A x=b$ is 0 flops example:

$$
A=\left[\begin{array}{lll}
0 & 1 & 0 \\
0 & 0 & 1 \\
1 & 0 & 0
\end{array}\right], \quad A^{-1}=A^{T}=\left[\begin{array}{lll}
0 & 0 & 1 \\
1 & 0 & 0 \\
0 & 1 & 0
\end{array}\right]
$$

## The factor-solve method for solving $A x=b$

- factor $A$ as a product of simple matrices (usually 2 or 3 ):

$$
A=A_{1} A_{2} \cdots A_{k}
$$

( $A_{i}$ diagonal, upper or lower triangular, etc)

- compute $x=A^{-1} b=A_{k}^{-1} \cdots A_{2}^{-1} A_{1}^{-1} b$ by solving $k$ 'easy' equations

$$
A_{1} x_{1}=b, \quad A_{2} x_{2}=x_{1}, \quad \ldots, \quad A_{k} x=x_{k-1}
$$

cost of factorization step usually dominates cost of solve step

## Equations with multiple righthand sides

$$
A x_{1}=b_{1}, \quad A x_{2}=b_{2}, \quad \ldots, \quad A x_{m}=b_{m}
$$

cost: one factorization plus $m$ solves

## LU factorization

every nonsingular matrix $A$ can be factored as

$$
A=P L U
$$

with $P$ a permutation matrix, $L$ lower triangular, $U$ upper triangular cost: $(2 / 3) n^{3}$ flops

## Solving linear equations by LU factorization

given: a set of linear equations $A x=b$, with $A$ nonsingular

1. $L U$ factorization: factor $A$ as $A=P L U\left((2 / 3) n^{3}\right.$ flops $)$
2. permutation: solve $P z_{1}=b$ (0 flops)
3. forward substitution: solve $L z_{2}=z_{1}$ ( $n^{2}$ flops)
4. backward substitution: solve $U x=z_{2}$ ( $n^{2}$ flops)
cost: $(2 / 3) n^{3}+2 n^{2} \approx(2 / 3) n^{3}$ for large $n$

## Sparse LU factorization

$$
A=P_{1} L U P_{2}
$$

- adding permutation matrix $P_{2}$ offers possibility of sparser $L, U$ (hence, cheaper factor and solve steps)
- $P_{1}$ and $P_{2}$ chosen (heuristically) to yield sparse $L, U$
- choice of $P_{1}$ and $P_{2}$ depends on sparsity pattern and values of $A$
- cost is usually much less than $(2 / 3) n^{3}$; exact value depends in a complicated way on $n$, number of zeros in $A$, sparsity pattern

## Cholesky factorization

every positive definite $A$ can be factored as

$$
A=L L^{T}
$$

with $L$ lower triangular
cost: $(1 / 3) n^{3}$ flops

Solving linear equations by Cholesky factorization
given: a set of linear equations $A x=b$, with $A \in \mathbf{S}_{++}^{n}$

1. Cholesky factorization: Factor $A$ as $A=L L^{T}\left((1 / 3) n^{3}\right.$ flops)
2. forward substitution: solve $L z_{1}=b$ ( $n^{2}$ flops)
3. backward substitution: solve $L^{T} x=z_{1}$ ( $n^{2}$ flops)
cost: $(1 / 3) n^{3}+2 n^{2} \approx(1 / 3) n^{3}$ for large $n$

## Sparse Cholesky factorization

$$
A=P L L^{T} P^{T}
$$

- adding permutation matrix $P$ offers possibility of sparser $L$
- $P$ chosen (heuristically) to yield sparse $L$
- choice of $P$ only depends on sparsity pattern of $A$ (unlike sparse LU)
- cost is usually much less than $(1 / 3) n^{3}$; exact value depends in a complicated way on $n$, number of zeros in $A$, sparsity pattern

## $\operatorname{LDL}^{\top}$ factorization

every nonsingular symmetric matrix $A$ can be factored as

$$
A=P L D L^{T} P^{T}
$$

with $P$ a permutation matrix, $L$ lower triangular, $D$ block diagonal with $1 \times 1$ or $2 \times 2$ diagonal blocks
cost: $(1 / 3) n^{3}$

- cost of solving symmetric sets of linear equations by $\operatorname{LDL}^{\top}$ factorization:

$$
\frac{1}{3} n^{3}+2 n^{2} \approx \frac{1}{3} n^{3}
$$

- for sparse $A$, can choose $P$ to yield sparse $L$; cost $\ll(1 / 3) n^{3}$

## Equations with structured sub-blocks

$$
\left[\begin{array}{ll}
A_{11} & A_{12}  \tag{1}\\
A_{21} & A_{22}
\end{array}\right]\left[\begin{array}{l}
x_{1} \\
x_{2}
\end{array}\right]=\left[\begin{array}{l}
b_{1} \\
b_{2}
\end{array}\right]
$$

- variables $x_{1} \in \mathbf{R}^{n_{1}}, x_{2} \in \mathbf{R}^{n_{2}}$; blocks $A_{i j} \in \mathbf{R}^{n_{i} \times n_{j}}$
- if $A_{11}$ is nonsingular, can eliminate $x_{1}: x_{1}=A_{11}^{-1}\left(b_{1}-A_{12} x_{2}\right)$
- to compute $x_{2}$, solve

$$
\left(A_{22}-A_{21} A_{11}^{-1} A_{12}\right) x_{2}=b_{2}-A_{21} A_{11}^{-1} b_{1}
$$

Solving linear equations by block elimination
given: a nonsingular set of linear equations (1), with $A_{11}$ nonsingular 1. form $A_{11}^{-1} A_{12}$ and $A_{11}^{-1} b_{1}$
2. form $S=A_{22}-A_{21} A_{11}^{-1} A_{12}$ and $\tilde{b}=b_{2}-A_{21} A_{11}^{-1} b_{1}$
3. determine $x_{2}$ by solving $S x_{2}=\tilde{b}$
4. determine $x_{1}$ by solving $A_{11} x_{1}=b_{1}-A_{12} x_{2}$

## Complexity of block elimination

## Dominant terms in flop count

- step 1: $f+n_{2} s$ ( $f$ is cost of factoring $A_{11} ; s$ is cost of solve step)
- step 2: $2 n_{2}^{2} n_{1}$ (cost dominated by product of $A_{21}$ and $A_{11}^{-1} A_{12}$ )
- step 3: $(2 / 3) n_{2}^{3}$ total: $f+n_{2} s+2 n_{2}^{2} n_{1}+(2 / 3) n_{2}^{3}$

## Examples

- general $A_{11}\left(f=(2 / 3) n_{1}^{3}, s=2 n_{1}^{2}\right)$ : no gain over standard method

$$
\text { \#flops }=\frac{2}{3} n_{1}^{3}+2 n_{1}^{2} n_{2}+2 n_{2}^{2} n_{1}+\frac{2}{3} n_{2}^{3}=\frac{2}{3}\left(n_{1}+n_{2}\right)^{3}
$$

- block elimination is useful for structured $A_{11}\left(f \ll n_{1}^{3}\right)$
- for example, diagonal ( $f=0, s=n_{1}$ ): \#flops $\approx 2 n_{2}^{2} n_{1}+(2 / 3) n_{2}^{3}$

## Structured matrix plus low rank term

$$
(A+B C) x=b
$$

- $A \in \mathbf{R}^{n \times n}, B \in \mathbf{R}^{n \times p}, C \in \mathbf{R}^{p \times n}$
- assume $A$ has structure ( $A x=b$ easy to solve)
first write as

$$
\left[\begin{array}{cc}
A & B \\
C & -I
\end{array}\right]\left[\begin{array}{l}
x \\
y
\end{array}\right]=\left[\begin{array}{l}
b \\
0
\end{array}\right]
$$

now apply block elimination: solve

$$
\left(I+C A^{-1} B\right) y=C A^{-1} b
$$

then solve $A x=b-B y$
this proves the matrix inversion lemma: if $A$ and $A+B C$ nonsingular,

$$
(A+B C)^{-1}=A^{-1}-A^{-1} B\left(I+C A^{-1} B\right)^{-1} C A^{-1}
$$

## Structured matrix plus low rank term

$$
(A+B C) x=b
$$

Example: $A$ diagonal, $B, C$ dense

- method 1: form $D=A+B C$, then solve $D x=b$
cost: $(2 / 3) n^{3}+2 p n^{2}$
- method 2 (via matrix inversion lemma): solve

$$
\begin{equation*}
\left(I+C A^{-1} B\right) y=C A^{-1} b \tag{2}
\end{equation*}
$$

then compute $x=A^{-1} b-A^{-1} B y$
total cost is dominated by (2): $2 p^{2} n+(2 / 3) p^{3}$ (i.e., linear in $n$ )

## Underdetermined linear equations

if $A \in \mathbf{R}^{p \times n}$ with $p<n, \mathbf{r a n k} A=p$,

$$
\{x \mid A x=b\}=\left\{F z+\hat{x} \mid z \in \mathbf{R}^{n-p}\right\}
$$

- $\hat{x}$ is (any) particular solution
- columns of $F \in \mathbf{R}^{n \times(n-p)}$ span nullspace of $A$
- there exist several numerical methods for computing $F$ (QR factorization, rectangular LU factorization, ...)
