L. Vandenberghe ECE133A (Fall 2024)

12. Cholesky factorization

- positive definite matrices
- examples
- Cholesky factorization
- complex positive definite matrices
- kernel methods

Definitions

• a symmetric matrix $A \in \mathbb{R}^{n \times n}$ is positive semidefinite if

$$x^T A x \ge 0$$
 for all x

• a symmetric matrix $A \in \mathbf{R}^{n \times n}$ is *positive definite* if

$$x^T A x > 0$$
 for all $x \neq 0$

this is a subset of the positive semidefinite matrices

note: if A is symmetric and $n \times n$, then $x^T A x$ is the function

$$x^{T}Ax = \sum_{i=1}^{n} \sum_{j=1}^{n} A_{ij}x_{i}x_{j} = \sum_{i=1}^{n} A_{ii}x_{i}^{2} + 2\sum_{i>j} A_{ij}x_{i}x_{j}$$

this is called a *quadratic form*

Example

$$A = \left[\begin{array}{cc} 9 & 6 \\ 6 & a \end{array} \right]$$

$$x^{T}Ax = 9x_{1}^{2} + 12x_{1}x_{2} + ax_{2}^{2} = (3x_{1} + 2x_{2})^{2} + (a - 4)x_{2}^{2}$$

• A is positive definite for a > 4

$$x^T A x > 0$$
 for all nonzero x

• A is positive semidefinite but not positive definite for a=4

$$x^T A x \ge 0$$
 for all x , $x^T A x = 0$ for $x = (2, -3)$

• A is not positive semidefinite for a < 4

$$x^T A x < 0$$
 for $x = (2, -3)$

Simple properties

• every positive definite matrix *A* is nonsingular

$$Ax = 0 \implies x^T Ax = 0 \implies x = 0$$

(last step follows from positive definiteness)

• every positive definite matrix A has positive diagonal elements

$$A_{ii} = e_i^T A e_i > 0$$

• every positive semidefinite matrix A has nonnegative diagonal elements

$$A_{ii} = e_i^T A e_i \ge 0$$

Schur complement

partition $n \times n$ symmetric matrix A as

$$A = \begin{bmatrix} A_{11} & A_{2:n,1}^T \\ A_{2:n,1} & A_{2:n,2:n} \end{bmatrix}$$

• the *Schur complement* of A_{11} is defined as the $(n-1) \times (n-1)$ matrix

$$S = A_{2:n,2:n} - \frac{1}{A_{11}} A_{2:n,1} A_{2:n,1}^T$$

• if A is positive definite, then S is positive definite to see this, take any $x \neq 0$ and define $y = -(A_{2:n,1}^T x)/A_{11}$; then

$$x^{T}Sx = \begin{bmatrix} y \\ x \end{bmatrix}^{T} \begin{bmatrix} A_{11} & A_{2:n,1}^{T} \\ A_{2:n,1} & A_{2:n,2:n} \end{bmatrix} \begin{bmatrix} y \\ x \end{bmatrix} > 0$$

because A is positive definite

Singular positive semidefinite matrices

- we mentioned that positive definite matrices are nonsingular (page 12.4)
- if A is positive semidefinite, but not positive definite, then it is singular

to see this, suppose A is positive semidefinite but not positive definite

- there exists a nonzero x with $x^T A x = 0$
- since *A* is positive semidefinite the following function is nonnegative:

$$f(t) = (x - tAx)^{T} A(x - tAx)$$

$$= x^{T} Ax - 2tx^{T} A^{2}x + t^{2}x^{T} A^{3}x$$

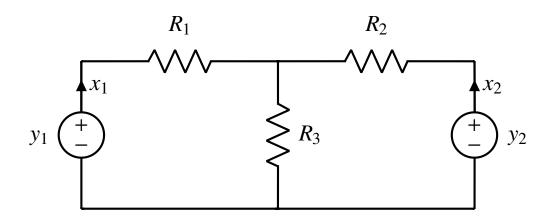

$$= -2t||Ax||^{2} + t^{2}x^{T} A^{3}x$$

- $f(t) \ge 0$ for all t is only possible if ||Ax|| = 0; therefore Ax = 0
- hence there exists a nonzero x with Ax = 0, so A is singular

Outline

- positive definite matrices
- examples
- Cholesky factorization
- complex positive definite matrices
- kernel methods

Exercise: resistor circuit

$$\begin{bmatrix} y_1 \\ y_2 \end{bmatrix} = \begin{bmatrix} R_1 + R_3 & R_3 \\ R_3 & R_2 + R_3 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}$$

show that the matrix

$$A = \left[\begin{array}{cc} R_1 + R_3 & R_3 \\ R_3 & R_2 + R_3 \end{array} \right]$$

is positive definite if R_1 , R_2 , R_3 are positive

Solution

Solution from physics

- $x^T A x = y^T x$ is the power delivered by sources, dissipated by resistors
- power dissipated by the resistors is positive unless both currents are zero

Algebraic solution

$$x^{T}Ax = (R_{1} + R_{3})x_{1}^{2} + 2R_{3}x_{1}x_{2} + (R_{2} + R_{3})x_{2}^{2}$$

$$= R_{1}x_{1}^{2} + R_{2}x_{2}^{2} + R_{3}(x_{1} + x_{2})^{2}$$

$$\geq 0$$

and
$$x^T A x = 0$$
 only if $x_1 = x_2 = 0$

Gram matrix

recall the definition of $Gram\ matrix$ of a matrix B (page 4.20):

$$A = B^T B$$

every Gram matrix is positive semidefinite

$$x^T A x = x^T B^T B x = ||Bx||^2 \ge 0 \quad \forall x$$

• a Gram matrix is positive definite if

$$x^T A x = x^T B^T B x = ||Bx||^2 > 0 \quad \forall x \neq 0$$

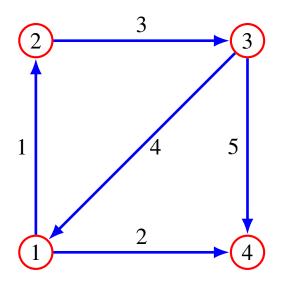

in other words, B has linearly independent columns

Graph Laplacian

recall definition of node-arc incidence matrix of a directed graph (page 3.29)

$$B_{ij} = \begin{cases} 1 & \text{if edge } j \text{ ends at vertex } i \\ -1 & \text{if edge } j \text{ starts at vertex } i \\ 0 & \text{otherwise} \end{cases}$$

assume there are no self-loops and at most one edge between any two vertices

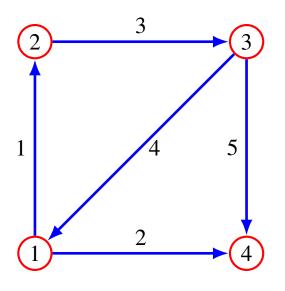

$$B = \begin{bmatrix} -1 & -1 & 0 & 1 & 0 \\ 1 & 0 & -1 & 0 & 0 \\ 0 & 0 & 1 & -1 & -1 \\ 0 & 1 & 0 & 0 & 1 \end{bmatrix}$$

Graph Laplacian

the positive semidefinite matrix $A = BB^T$ is called the *Laplacian* of the graph

$$A_{ij} = \begin{cases} \text{ degree of vertex } i & \text{if } i = j \\ -1 & \text{if } i \neq j \text{ and vertices } i \text{ and } j \text{ are adjacent} \\ 0 & \text{otherwise} \end{cases}$$

the degree of a vertex is the number of edges incident to it

$$A = BB^{T} = \begin{bmatrix} 3 & -1 & -1 & -1 \\ -1 & 2 & -1 & 0 \\ -1 & -1 & 3 & -1 \\ -1 & 0 & -1 & 2 \end{bmatrix}$$

Laplacian quadratic form

recall the interpretation of matrix-vector multiplication with \boldsymbol{B}^T (page 3.31)

• if y is vector of node potentials, then B^Ty contains potential differences:

$$(B^T y)_j = y_k - y_l$$
 if edge j goes from vertex l to k

• $y^TAy = y^TBB^Ty$ is the sum of squared potential differences

$$y^{T}Ay = ||B^{T}y||^{2} = \sum_{\text{edges } i \to j} (y_{j} - y_{i})^{2}$$

this is also known as the *Dirichlet energy* function

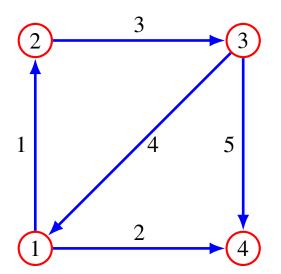

Example: for the graph on the previous page

$$y^{T}Ay = (y_2 - y_1)^2 + (y_4 - y_1)^2 + (y_3 - y_2)^2 + (y_1 - y_3)^2 + (y_4 - y_3)^2$$

Weighted graph Laplacian

- we associate a nonnegative weight w_k with edge k
- the weighted graph Laplacian is the matrix $A = B \operatorname{diag}(w)B^T$ $(\mathbf{diag}(w))$ is the diagonal matrix with vector w on its diagonal)

$$A_{ij} = \begin{cases} \sum\limits_{k \in \mathcal{N}_i} w_k & \text{if } i = j \quad \text{(where } \mathcal{N}_i \text{ are the edges incident to vertex } i\text{)} \\ -w_k & \text{if } i \neq j \text{ and edge } k \text{ is between vertices } i \text{ and } j \\ 0 & \text{otherwise} \end{cases}$$

$$A = \begin{bmatrix} w_1 + w_2 + w_4 & -w_1 & -w_4 & -w_2 \\ -w_1 & w_1 + w_3 & -w_3 & 0 \\ -w_4 & -w_3 & w_3 + w_4 + w_5 & -w_5 \\ -w_2 & 0 & -w_5 & w_2 + w_5 \end{bmatrix}$$

this is the conductance matrix of a resistive circuit (w_k is conductance in branch k)

Outline

- positive definite matrices
- examples
- Cholesky factorization
- complex positive definite matrices
- kernel methods

Cholesky factorization

every positive definite matrix $A \in \mathbf{R}^{n \times n}$ can be factored as

$$A = R^T R$$

where R is upper triangular with positive diagonal elements

- complexity of computing R is $\frac{1}{3}n^3$ flops
- *R* is called the *Cholesky factor* of *A*
- can be interpreted as "square root" of a positive definite matrix
- gives a practical method for testing positive definiteness

Cholesky factorization algorithm

$$\begin{bmatrix} A_{11} & A_{1,2:n} \\ A_{2:n,1} & A_{2:n,2:n} \end{bmatrix} = \begin{bmatrix} R_{11} & 0 \\ R_{1,2:n}^T & R_{2:n,2:n}^T \end{bmatrix} \begin{bmatrix} R_{11} & R_{1,2:n} \\ 0 & R_{2:n,2:n} \end{bmatrix}$$
$$= \begin{bmatrix} R_{11}^2 & R_{11}R_{1,2:n} \\ R_{11}R_{1,2:n}^T & R_{1,2:n}^T R_{1,2:n} + R_{2:n,2:n}^T R_{2:n,2:n} \end{bmatrix}$$

1. compute first row of *R*:

$$R_{11} = \sqrt{A_{11}}, \qquad R_{1,2:n} = \frac{1}{R_{11}} A_{1,2:n}$$

2. compute 2, 2 block $R_{2:n,2:n}$ from

$$A_{2:n,2:n} - R_{1,2:n}^T R_{1,2:n} = R_{2:n,2:n}^T R_{2:n,2:n}$$

this is a Cholesky factorization of order n-1

Discussion

the algorithm works for positive definite A of size $n \times n$

- step 1: if A is positive definite then $A_{11} > 0$
- step 2: if *A* is positive definite, then

$$A_{2:n,2:n} - R_{1,2:n}^T R_{1,2:n} = A_{2:n,2:n} - \frac{1}{A_{11}} A_{2:n,1} A_{2:n,1}^T$$

is positive definite (see page 12.5)

- hence the algorithm works for n = m if it works for n = m 1
- it obviously works for n = 1; therefore it works for all n

Example

$$\begin{bmatrix} 25 & 15 & -5 \\ 15 & 18 & 0 \\ -5 & 0 & 11 \end{bmatrix} = \begin{bmatrix} R_{11} & 0 & 0 \\ R_{12} & R_{22} & 0 \\ R_{13} & R_{23} & R_{33} \end{bmatrix} \begin{bmatrix} R_{11} & R_{12} & R_{13} \\ 0 & R_{22} & R_{23} \\ 0 & 0 & R_{33} \end{bmatrix}$$

$$= \begin{bmatrix} 5 & 0 & 0 \\ 3 & 3 & 0 \\ -1 & 1 & 3 \end{bmatrix} \begin{bmatrix} 5 & 3 & -1 \\ 0 & 3 & 1 \\ 0 & 0 & 3 \end{bmatrix}$$

Example

$$\begin{bmatrix} 25 & 15 & -5 \\ 15 & 18 & 0 \\ -5 & 0 & 11 \end{bmatrix} = \begin{bmatrix} R_{11} & 0 & 0 \\ R_{12} & R_{22} & 0 \\ R_{13} & R_{23} & R_{33} \end{bmatrix} \begin{bmatrix} R_{11} & R_{12} & R_{13} \\ 0 & R_{22} & R_{23} \\ 0 & 0 & R_{33} \end{bmatrix}$$

• first row of R

$$\begin{bmatrix} 25 & 15 & -5 \\ 15 & 18 & 0 \\ -5 & 0 & 11 \end{bmatrix} = \begin{bmatrix} 5 & 0 & 0 \\ 3 & R_{22} & 0 \\ -1 & R_{23} & R_{33} \end{bmatrix} \begin{bmatrix} 5 & 3 & -1 \\ 0 & R_{22} & R_{23} \\ 0 & 0 & R_{33} \end{bmatrix}$$

second row of R

$$\begin{bmatrix} 18 & 0 \\ 0 & 11 \end{bmatrix} - \begin{bmatrix} 3 \\ -1 \end{bmatrix} \begin{bmatrix} 3 & -1 \end{bmatrix} = \begin{bmatrix} R_{22} & 0 \\ R_{23} & R_{33} \end{bmatrix} \begin{bmatrix} R_{22} & R_{23} \\ 0 & R_{33} \end{bmatrix}$$
$$\begin{bmatrix} 9 & 3 \\ 3 & 10 \end{bmatrix} = \begin{bmatrix} 3 & 0 \\ 1 & R_{33} \end{bmatrix} \begin{bmatrix} 3 & 1 \\ 0 & R_{33} \end{bmatrix}$$

• third column of R: $10 - 1 = R_{33}^2$, *i.e.*, $R_{33} = 3$

Solving equations with positive definite *A*

solve Ax = b with A a positive definite $n \times n$ matrix

Algorithm

- factor A as $A = R^T R$
- solve $R^T R x = b$
 - solve $R^T y = b$ by forward substitution
 - solve Rx = y by back substitution

Complexity: $\frac{1}{3}n^3 + 2n^2 \sim \frac{1}{3}n^3$ flops

- factorization: $\frac{1}{3}n^3$
- forward and backward substitution: $2n^2$

Cholesky factorization of Gram matrix

- suppose B is an $m \times n$ matrix with linearly independent columns
- the Gram matrix $A = B^T B$ is positive definite (page 4.20)

two methods for computing the Cholesky factor of A, given B

1. compute $A = B^T B$, then Cholesky factorization of A

$$A = R^T R$$

2. compute QR factorization B = QR; since

$$A = B^T B = R^T Q^T Q R = R^T R$$

the matrix R is the Cholesky factor of A

Example

$$B = \begin{bmatrix} 3 & -6 \\ 4 & -8 \\ 0 & 1 \end{bmatrix}, \qquad A = B^T B = \begin{bmatrix} 25 & -50 \\ -50 & 101 \end{bmatrix}$$

1. Cholesky factorization:

$$A = \left[\begin{array}{cc} 5 & 0 \\ -10 & 1 \end{array} \right] \left[\begin{array}{cc} 5 & -10 \\ 0 & 1 \end{array} \right]$$

2. QR factorization

$$B = \begin{bmatrix} 3 & -6 \\ 4 & -8 \\ 0 & 1 \end{bmatrix} = \begin{bmatrix} 3/5 & 0 \\ 4/5 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} 5 & -10 \\ 0 & 1 \end{bmatrix}$$

Comparison of the two methods

Numerical stability: QR factorization method is more stable

- see the example on page 8.16
- QR method computes R without "squaring" B (i.e., forming B^TB)
- this is important when the columns of *B* are "almost" linearly dependent

Complexity

• method 1: cost of symmetric product B^TB plus Cholesky factorization

$$mn^2 + \frac{1}{3}n^3$$
 flops

- method 2: $2mn^2$ flops for QR factorization
- method 1 is faster but only by a factor of at most two (if $m \gg n$)

Sparse positive definite matrices

Cholesky factorization of dense matrices

- $\frac{1}{3}n^3$ flops
- on a standard computer: a few seconds or less, for *n* up to several 1000

Cholesky factorization of sparse matrices

- if A is very sparse, R is often (but not always) sparse
- if R is sparse, the cost of the factorization is much less than $\frac{1}{3}n^3$
- \bullet exact cost depends on n, number of nonzero elements, sparsity pattern
- very large sets of equations can be solved by exploiting sparsity

Cholesky factorization 12.23

Sparse Cholesky factorization

if A is sparse and positive definite, it is usually factored as

$$A = PR^T RP^T$$

P a permutation matrix; R upper triangular with positive diagonal elements

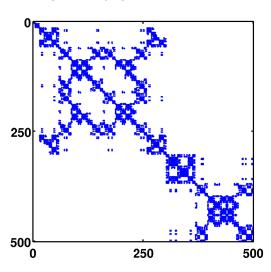

Interpretation: we permute the rows and columns of A and factor

$$P^T A P = R^T R$$

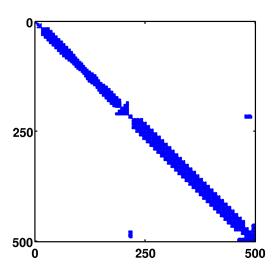

- choice of permutation greatly affects the sparsity R
- there exist several heuristic methods for choosing a good permutation

Example

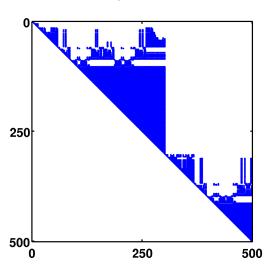

sparsity pattern of A

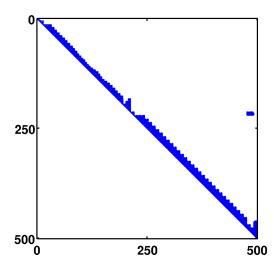

pattern of P^TAP

Cholesky factor of \boldsymbol{A}

Cholesky factor of P^TAP

Cholesky factorization 12.25

Solving sparse positive definite equations

solve Ax = b with A a sparse positive definite matrix

Algorithm

- 1. compute sparse Cholesky factorization $A = PR^TRP^T$
- 2. permute right-hand side: $c := P^T b$
- 3. solve $R^T y = c$ by forward substitution
- 4. solve Rz = y by back substitution
- 5. permute solution: x := Pz

Outline

- positive definite matrices
- examples
- Cholesky factorization
- complex positive definite matrices
- kernel methods

Quadratic form

suppose A is $n \times n$ and Hermitian $(A_{ij} = \bar{A}_{ji})$

$$x^{H}Ax = \sum_{i=1}^{n} \sum_{j=1}^{n} A_{ij}\bar{x}_{i}x_{j}$$

$$= \sum_{i=1}^{n} A_{ii}|x_{i}|^{2} + \sum_{i>j} (A_{ij}\bar{x}_{i}x_{j} + \bar{A}_{ij}x_{i}\bar{x}_{j})$$

$$= \sum_{i=1}^{n} A_{ii}|x_{i}|^{2} + 2\operatorname{Re} \sum_{i>j} A_{ij}\bar{x}_{i}x_{j}$$

note that $x^H A x$ is real for all $x \in \mathbb{C}^n$

Complex positive definite matrices

• a Hermitian $n \times n$ matrix A is positive semidefinite if

$$x^H A x \ge 0$$
 for all $x \in \mathbb{C}^n$

• a Hermitian $n \times n$ matrix A is positive definite if

$$x^H Ax > 0$$
 for all nonzero $x \in \mathbb{C}^n$

Cholesky factorization

every positive definite matrix $A \in \mathbb{C}^{n \times n}$ can be factored as

$$A = R^H R$$

where R is upper triangular with positive real diagonal elements

Outline

- positive definite matrices
- examples
- Cholesky factorization
- complex positive definite matrices
- kernel methods

Regularized least squares model fitting

we revisit the data fitting problem with linear-in-parameters model (page 9.9)

$$\hat{f}(x) = \theta_1 f_1(x) + \theta_2 f_2(x) + \dots + \theta_p f_p(x)$$
$$= \theta^T F(x)$$

• $F(x) = (f_1(x), \dots, f_p(x))$ is a p-vector of basis functions $f_1(x), \dots, f_p(x)$

Regularized least squares model fitting (page 10.7)

minimize
$$\sum_{k=1}^{N} \left(\theta^T F(x^{(k)}) - y^{(k)} \right)^2 + \lambda \sum_{j=1}^{p} \theta_j^2$$

- $(x^{(1)}, y^{(1)}), \dots, (x^{(N)}, y^{(N)})$ are N examples
- to simplify notation, we add regularization for all coefficients $\theta_1, \ldots, \theta_p$
- next discussion can be modified to handle $f_1(x) = 1$, regularization $\sum_{j=2}^p \theta_j^2$

Cholesky factorization

Regularized least squares problem in matrix notation

minimize
$$||A\theta - b||^2 + \lambda ||\theta||^2$$

• A has size $N \times p$ (number of examples \times number of basis functions)

$$A = \begin{bmatrix} F(x^{(1)})^T \\ F(x^{(2)})^T \\ \vdots \\ F(x^{(N)})^T \end{bmatrix} = \begin{bmatrix} f_1(x^{(1)}) & f_2(x^{(1)}) & \cdots & f_p(x^{(1)}) \\ f_1(x^{(2)}) & f_2(x^{(2)}) & \cdots & f_p(x^{(2)}) \\ \vdots & \vdots & & \vdots \\ f_1(x^{(N)}) & f_2(x^{(N)}) & \cdots & f_p(x^{(N)}) \end{bmatrix}$$

- *b* is the *N*-vector $b = (y^{(1)}, ..., y^{(N)})$
- we discuss methods for problems with $N \ll p$ (A is very wide)
- the equivalent "stacked" least squares problem (p.10.3) has size $(p + N) \times p$
- QR factorization method may be too expensive when $N \ll p$

Solution of regularized LS problem

from the normal equations:

$$\hat{\theta} = (A^T A + \lambda I)^{-1} A^T b = A^T (AA^T + \lambda I)^{-1} b$$

second expression follows from the "push-through" identity

$$(A^{T}A + \lambda I)^{-1}A^{T} = A^{T}(AA^{T} + \lambda I)^{-1}$$

this is easily proved, by writing it as $A^T(AA^T + \lambda I) = (A^TA + \lambda I)A^T$

• from the second expression for $\hat{\theta}$ and the definition of A,

$$\hat{f}(x) = \hat{\theta}^T F(x) = w^T A F(x) = \sum_{i=1}^N w_i F(x^{(i)})^T F(x)$$

where
$$w = (AA^T + \lambda I)^{-1}b$$

Algorithm

1. compute the $N \times N$ matrix $Q = AA^T$, which has elements

$$Q_{ij} = F(x^{(i)})^T F(x^{(j)}), \quad i, j = 1, \dots, N$$

2. use a Cholesky factorization to solve the equation

$$(Q + \lambda I)w = b$$

Remarks

• $\hat{\theta} = A^T w$ is not needed; w is sufficient to evaluate the function $\hat{f}(x)$:

$$\hat{f}(x) = \sum_{i=1}^{N} w_i F(x^{(i)})^T F(x)$$

• complexity: $\frac{1}{3}N^3$ flops for factorization plus cost of computing Q

Example: multivariate polynomials

 $\hat{f}(x)$ is a polynomial of degree d (or less) in n variables $x = (x_1, \dots, x_n)$

• $\hat{f}(x)$ is a linear combination of all possible monomials

$$x_1^{k_1}x_2^{k_2}\cdots x_n^{k_n}$$

where k_1, \ldots, k_n are nonnegative integers with $k_1 + k_2 + \cdots + k_n \le d$

• number of different monomials is

$$\left(\begin{array}{c} n+d \\ n \end{array}\right) = \frac{(n+d)!}{n! \ d!}$$

Example: for n = 2, d = 3 there are ten monomials

1,
$$x_1$$
, x_2 , x_1^2 , x_1x_2 , x_2^2 , x_1^3 , $x_1^2x_2$, $x_1x_2^2$, x_2^3

Multinomial formula

$$(x_0 + x_1 + \dots + x_n)^d = \sum_{k_0 + \dots + k_n = d} \frac{(d+1)!}{k_0! \, k_1! \, \dots \, k_n!} \, x_0^{k_0} x_1^{k_1} \dots x_n^{k_n}$$

sum is over all nonnegative integers k_0, k_1, \ldots, k_n with sum d

• setting $x_0 = 1$ gives

$$(1+x_1+x_2+\cdots+x_n)^d = \sum_{k_1+\cdots+k_n\leq d} c_{k_1k_2\cdots k_n} x_1^{k_1} x_2^{k_2}\cdots x_n^{k_n}$$

- the sum includes all monomials of degree d or less with variables x_1, \ldots, x_n
- coefficient $c_{k_1k_2\cdots k_n}$ is defined as

$$c_{k_1 k_2 \cdots k_n} = \frac{(d+1)!}{k_0! \ k_1! \ k_2! \cdots k_n!}$$
 with $k_0 = d - k_1 - \cdots - k_n$

Vector of monomials

write polynomial of degree d or less, with variables $x \in \mathbf{R}^n$, as

$$\hat{f}(x) = \theta^T F(x)$$

• *F*(*x*) is vector of basis functions

$$\sqrt{c_{k_1\cdots k_n}} x_1^{k_1} x_2^{k_2} \cdots x_n^{k_n}$$
 for all $k_1 + k_2 + \cdots + k_n \le d$

- length of F(x) is p = (n+d)!/(n! d!)
- multinomial formula gives simple formula for inner products $F(u)^T F(v)$:

$$F(u)^{T}F(v) = \sum_{k_{1}+\dots+k_{n}\leq d} c_{k_{1}k_{2}\dots k_{n}} (u_{1}^{k_{1}}\dots u_{n}^{k_{n}})(v_{1}^{k_{1}}\dots v_{n}^{k_{n}})$$
$$= (1+u_{1}v_{1}+\dots+u_{n}v_{n})^{d}$$

• only 2n + 1 flops needed for inner product of length p = (n + d)!/(n! d!)

Example

vector of monomials of degree d = 3 or less in n = 2 variables

$$F(u)^{T}F(v) = \begin{bmatrix} 1 \\ \sqrt{3}u_{1} \\ \sqrt{3}u_{2} \\ \sqrt{3}u_{1}^{2} \\ \sqrt{6}u_{1}u_{2} \\ \sqrt{3}u_{1}^{2} \\ \sqrt{3}u_{1}^{2} \\ \sqrt{3}u_{1}^{2}u_{2} \\ \sqrt{3}u_{1}u_{2}^{2} \\ \sqrt{3}u_{1}u_{2}^{2} \\ u_{3}^{3} \end{bmatrix}^{T} \begin{bmatrix} 1 \\ \sqrt{3}v_{1} \\ \sqrt{3}v_{2} \\ \sqrt{3}v_{1}^{2} \\ \sqrt{3}v_{1}^{2}v_{2} \\ \sqrt{3}v_{1}v_{2}^{2} \\ \sqrt{3}v_{1}v_{2}^{2} \\ v_{3}^{3} \end{bmatrix}$$

$$= (1 + u_1v_1 + u_2v_2)^3$$

Least squares fitting of multivariate polynomials

fit polynomial of n variables, degree $\leq d$, to points $(x^{(1)}, y^{(1)}), \ldots, (x^{(N)}, y^{(N)})$

Algorithm (see page 12.32)

1. compute the $N \times N$ matrix Q with elements

$$Q_{ij} = K(x^{(i)}, x^{(j)})$$
 where $K(u, v) = (1 + u^T v)^d$

- 2. use a Cholesky factorization to solve the equation $(Q + \lambda I)w = b$
- the fitted polynomial is

$$\hat{f}(x) = \sum_{i=1}^{N} w_i K(x^{(i)}, x) = \sum_{i=1}^{N} w_i (1 + (x^{(i)})^T x)^d$$

• complexity: nN^2 flops for computing Q, plus $\frac{1}{3}N^3$ for the factorization, *i.e.*,

$$nN^2 + \frac{1}{3}N^3$$
 flops

Kernel methods

Kernel function: a generalized inner product K(u, v)

- K(u, v) is inner product of vectors of basis functions F(u) and F(v)
- F(u) may be infinite-dimensional
- kernel methods work with K(u, v) directly, do not require F(u)

Examples

- the polynomial kernel function $K(u, v) = (1 + u^T v)^d$
- the Gaussian radial basis function kernel

$$K(u, v) = \exp\left(-\frac{\|u - v\|^2}{2\sigma^2}\right)$$

kernels exist for computing with graphs, texts, strings of symbols, ...

Example: handwritten digit classification

we apply the method of page 12.37 to least squares classification

- training set is 10000 images from MNIST data set (≈ 1000 examples per digit)
- vector x is vector of pixel intensities (size $n = 28^2 = 784$)
- we use the polynomial kernel with degree d=3:

$$K(u, v) = (1 + u^T v)^3$$

hence F(z) has length p = (n + d)!/(n! d!) = 80931145

we calculate ten Boolean classifiers

$$\hat{f}_k(x) = \operatorname{sign}(\tilde{f}_k(x)), \quad k = 1, \dots 10$$

 $\hat{f}_k(x)$ distinguishes digit k-1 (outcome +1) form other digits (outcome -1)

the Boolean classifiers are combined in the multi-class classifier

$$\hat{f}(x) = \underset{k=1,...,10}{\operatorname{argmax}} \tilde{f}_k(x)$$

Least squares Boolean classifier

Algorithm: compute Boolean classifier for digit k-1 versus the rest

1. compute $N \times N$ matrix Q with elements

$$Q_{ij} = (1 + (x^{(i)})^T x^{(j)})^d, \quad i, j = 1, \dots, N$$

2. define *N*-vector $b = (y^{(1)}, \dots, y^{(N)})$ with elements

$$y^{(i)} = \begin{cases} +1 & x^{(i)} \text{ is an example of digit } k - 1 \\ -1 & \text{otherwise} \end{cases}$$

3. solve the equation $(Q + \lambda I)w = b$

the solution w gives the Boolean classifier for digit k-1 versus rest

$$\tilde{f}_k(x) = \sum_{i=1}^{N} w_i (1 + (x^{(i)})^T x)^d$$

Complexity

- the matrix Q is the same for each of the ten Boolean classifiers
- hence, only the right-hand side of the equation

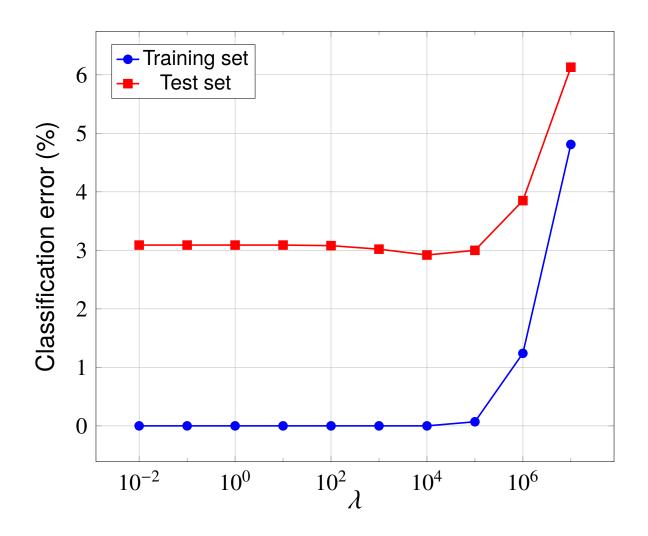

$$(Q + \lambda I)w = y^{d}$$

is different for each Boolean classifier

Complexity

- constructing Q requires $N^2/2$ inner products of length n: nN^2 flops
- Cholesky factorization of $Q + \lambda I$: $\frac{1}{3}N^3$ flops
- solve the equation $(Q + \lambda I)w = y^d$ for the 10 right-hand sides: $20N^2$ flops
- total is $\frac{1}{3}N^3 + nN^2$

Classification error

percentage of misclassified digits versus λ

Cholesky factorization 12.42
